Examples - which flavor of T?

Paired t-test

t-test: More juice po squeeze?

Examples - which flavor of T?

Last lecture we introduced the T test for two independent samples

In this lecture we will extend our t-testing framework to consider what happens when those samples are NOT independent.

Examples - which flavor of T?

Imagine for example that we want to show that weight is different among males and females in the United States. Imagine we have data from 100 randomly sampled males and 100 randomly sampled females in the United States.

We would test the null hypothesis that there is no difference between the mean weight of men and women in the united states

$$\bar{X}_{(group_a)} = \bar{X}_{(group_b)}$$

Example: Weight by gender

L26: More flavors of T

standard

Paired t-test

t-test: More juice pe squeeze?

Examples - which flavor of T?

Would we consider these samples independent?

Paired t-te

t-test: More juice per

Examples - which flavor of

standard two-sample t-test

We want to compare the mean weight for each group, and use the standard error of the weights of these groups to calculate a t-test. This helps us to understand if the difference in the means is larger than we might see due to the variability of the weights in our observations.

we would calculate

$$t = \frac{x_{groupa} - x_{groupb}}{\sqrt{\frac{S_{groupa}^2 + S_{groupb}^2}{n}}}$$

and compare this to a t-distribution at our chosen critical point with appropriate degrees of freedom

To illustrate this example, I have simulated data for males and females using the mean and standard deviation of weights in the United States taken from the CDC NHANES data

standard two-sample t-test

Paired t-test

Example small study of diet Examples - which flavor of T?

```
# A tibble: 2 \times 4
##
             sample mean sample sd length
      sex
##
      \langle fct \rangle
                     <dbl>
                                 <dbl>
                                          <int>
## 1 F
                      171.
                                  29.1
                                            100
## 2 M
                      191.
                                  28.9
                                             100
```

geom_histogram(data=subset(weights,sex == 'F'),binwidth=5,fill = "blue", col=

 $theme_minimal(base_size = 15)$

ggplot(weights.aes(x=weight1)) +

Notice that I am using two geom_histogram statements to lay the histograms on top of one another rather than using a "fill" statement in one geom_histogram.

I can overlay the histograms for these data with this code:

Two sample t-test

##
                          191.3629
```

In this example we have measured randomly selected males and females and we have no reason to believe their measurements are correlated. So a two-sample simple t-test is a reasonable approach.

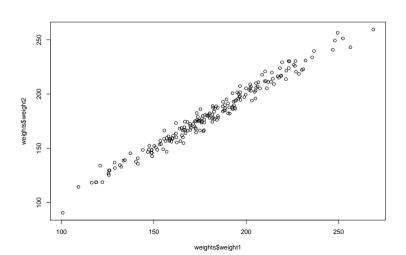

What happens if we imagine that these 200 individuals are all invited to participate in a weight loss trial.

We have their baseline weight, and after 6 months of participation in the trial they are weighted again.

What would we assume about the independence of our measures now?

Independent vs. non-independent samples

Using r to graph the post-trial weight against the pre-trial weight we can see that these are correlated

L26: More flavors of T

standard two-sample t-test

Paired t-test

t-test: More juice per squeeze?

Examples - which flavor of T?

For each individual in this study, we will will compare their weight after 6 months in the trial to their weight at baseline. Now we have broken our assumption (needed for the Student's t-test) that the measurements in the two groups (pre and post) are independent of each other.

We would expect that each person's weight at 6 month follow up will be closely related to their own weight at baseline. We would also expect that the variation in weight within one person will be much less than the variation in weight between people.

In this case, because I have simulated the data, I know that this hypothetical weight loss program results in an average weight loss of 5 pounds with a standard deviation of 5 pounds.

Let's take a look at what happens when we use this Student's T test to compare weights before and after the intervention without taking into account the relationship of these measurements:

If we do not take into account the paired structure of the data, we are testing the null hypothesis

$$ar{X}_{(weight pretrial)} = ar{X}_{(weight posttrial)}$$

and our t-test would be based on

$$t = rac{\overline{X_{(weightpretrial)}} - \overline{X_{(weightposttrial)}}}{\sqrt{\left(rac{S_1^2}{n_1} + rac{S_2^2}{n_2}
ight)}}$$

t.test(weights\$weight1, weights\$weight3, data=weights)

xample small study of die xamples - which flavor of

```
##
##
   Welch Two Sample t-test
##
## data: weights$weight1 and weights$weight3
  t = 1.6059, df = 397.72, p-value = 0.1091
## alternative hypothesis: true difference in means is not equal to 0
## 95 percent confidence interval:
  -1.122791 11.139438
## sample estimates:
## mean of x mean of y
##
   180.9544 175.9460
```

Example small study of diel

Examples - which flavor of

T?

We see that the estimated difference in weight is close to 5 pounds, but the results are not statistically significant. If we do not account for the relatedness of these measurements there is too much "noise" or variation between the measurements to see the "signal" or the true difference in means.

The solution to this problem is to look at the measurements in pairs and base our statistical testing on the variability in the difference between the pre and post intervention measures of weight.

Paired t-test

squeeze?

Example small study of die

Examples - which flavor of T?

Here we see that the estimate of difference is unchanged, but the t-test is now using the standard deviation of the difference (4.85) rather than the standard deviation of weights between people at each time point(30.77 and 31.6) to determine whether this difference is statistically significant.

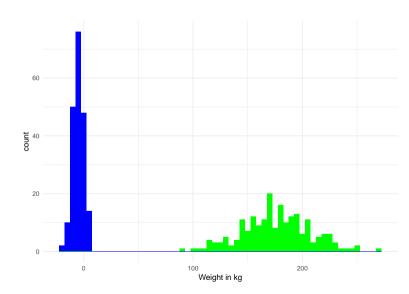

With the paired test, our value of t is much higher and our results are statistically significant.

Example small study of die Examples - which flavor of

If we graph the mean values and distribution of the difference between pre and post trial weight, and the overall weights post trial we can see that the variability is much smaller for the difference.

```
\begin{split} & \text{ggplot()} + \\ & \text{geom\_histogram(data = weights, aes(x = weight3), binwidth=5, fill="green")} + \\ & \text{geom\_histogram(data = weights, aes(x = dif2), binwidth=5, fill="blue")} + \\ & \text{labs(} \times = \text{"Weight in kg")} + \\ & \text{theme\_minimal(base\_size} = 15) \end{split}
```

- Once the problem has been stated, the next step is to determine a plan to best answer the question. One of the tenets of design is to maximize efficiency.
- ▶ When data are paired a paired test greatly maximizes the efficiency by removing the noise introduced by between-subject variability.

When is a paired design the appropriate design?

- Cross -over or before and after studies in our weigh-loss example we were looking at measures before and after participation...
 - ▶ When "the treatment alleviates a condition rather than affects a cure." (Hills and Armitrage, 1979)
 - ► The effect of treatment is short-term. After *x* amount of time, participants return to baseline.
 - ► The *x* above refers to the wash-out period. Before applying the second treatment, participants should have enough time to reach their baseline level. Otherwise there may be a carry over effect.

standard two-sample t-test

t-test: More juice per

squeeze?

Example small study of die

Examples - which flavor of T?

Considerations for before/after or cross-over studies - The time between the alternative treatments isn't so long as to introduce confounding by other factors. - For example, if you waited a year between applying treatments, other things may have changed in the world or in a person's life that affects the outcome. - Thus, there is a balance between waiting too long or not waiting long enough.

If we wanted to look at changes in individual related to a treatment what other type of design might we consider?
